

# Math 2283 - Introduction to Logic

Quiz #11 - 2008.11.24

Solutions

---

Consider the following relation  $D$  defined as follows:

$$xDy = x - y, \text{ in the case that } x \geq y$$

$$xDy = y - x, \text{ in the case that } x \leq y$$

Definitions to remember:

An operation  $O$  is commutative if for any  $x$  and  $y$ :  $xOy = yOx$ .

An operation  $O$  is associative if for any  $x$ ,  $y$  and  $z$ :  $xO(yOz) = (xOy)Oz$ .

An operation  $O$  is right-invertible if for any  $x$ ,  $y$  one can find a  $z$  such that :  $x = yOz$ .

An operation  $O$  is left-invertible if for any  $x$ ,  $y$  one can find a  $z$  such that :  $x = zOy$ .

1) Is the operation  $D$  commutative?

Yes, clearly  $xGy = yGx$  since all we do is take the larger of  $x$  and  $y$  and subtract the smaller one off, it does not matter which order  $x$  and  $y$  appear in the formula  $xGy$ .

2) Is the operation  $D$  associative?

No, the operation is not associative. As an example, consider  $x = 10$ ,  $y = 5$  and  $z = 7$ . Then  $10D(5D7) = 10D2 = 8$  while  $(10D5)D7 = 5D7 = 2$ .

3) Is the operation  $D$  left- or right-invertible?

Let us first look at right-invertible. The question is, given an arbitrary pair of numbers  $x$  and  $y$ , can we find a  $z$  such that  $x = yDz$ ? The answer is no. Consider the case of  $x = -1$  and  $y = 0$ . Then we have the following expression that we need to solve for  $z$  in:  $-1 = 0Dz$ . The only potential values that would work are  $z = 1$  and  $z = -1$ . But  $0D(-1) = 1$  and  $0D1 = 1$ . Similarly,  $D$  is also not right invertible by the same reason (and that  $D$  is commutative).
